Let's Start!

Database Background Processes

Learning Outcome:

Exchange written and spoken information on principles, concepts, data base objects related to query analysis, and data base engines.
Describe relational database, its concepts, and principles in spoken or written texts.

Can Do Statements:

- I can say what a process in an operating system is.
- I can say how a user or client process is created or maintained.
- I can talk about instance memory structures.

Ask your partner:

- How do you think an operating system can handle multiple users at the same time?
- Do you think a user can access to the background process in a database? Why?

Let's Explore!

Susan is trying to understand database background processes, but she can't do it alone.

Instructions: Read the text below.

- Susan:** Jeff, you have to help me out! If I don't understand these server processes for next week, I will be in trouble!
- Jeff:** Susan, calm down. First of all, do you know what a process in an operating system is?
- Susan:** It is a mechanism that runs a series of steps. People call this process jobs or tasks, right?
- Jeff:** Exactly. Now, there are three types of processes; background, user and server processes.
- Susan:** Well, in a background process, different functions ought to be consolidated, so we don't need many programs to handle and we can monitor other processes. When we use parallelism to create a better performance, reliability in the system goes up.
- Jeff:** Exactly! User processes are a little different. Their main function is to run software code of an application program or tool. They ought to be created and maintained for this sole purpose.
- Susan:** Okay. But they can use separate machines for background and user processes, can't they?
- Jeff:** That's right. You are already taking a grasp of these concepts. They also manage the communication with the server processes through the interface of different programs.
- Susan:** But then, what do the server processes do?
- Jeff:** They act as a bridge between the background and user processes; they handle the request and interact with the database. All the processes ought to be configured according to the number of users to minimize the work and maximize the use of resources.
- Susan:** Okay, I get it now. Last question, what's the purpose of instance memory structures?
- Jeff:** They store the program code, the shared data, even the private data. Their main objective is to contain and control all the data in the database. Sometimes, these memory structures are internally created for the exclusive use of the processes so users can't even see them.

Let's Practice!

When you have a doubt about processes, you immediately look for answers.

Instructions: Write the missing words. Use capital letters where necessary. Use: When running, will need, I'll clarify, If you have, people will, If you use.

_____ any doubt about what a process is in an operating system, _____ them promptly. A process is a mechanism that runs or operates the different stages of a process. _____ the words task or job, _____ coin those words instead of the word "process".

When talking about a process, you will have to enumerate the three kinds of it: background, user and server. _____ the background process, you _____ to be sure about the consolidation of the functions.

Let's Practice!

This is how a client process ought to be defined!

Instructions: Draw a line to match the sentence in column A to a concept in column B.

COLUMN A

1. Its main function is to run a software code of an application program or tool.
2. They can use separate machines for background and user processes.
3. They manage communication with the server process through the interface of different programs.

COLUMN B

- a. Connection with the server process
- b. Main Function
- c. Different machines for different processes

Extension Activity

I can know more about processes in an operating system.

Instructions: Complete the following steps. Fill in the Self-Assessment.

- Look for more information about processes in an operating system.
- Create a small poster with the main characteristics of processes in an operating system. Include characteristics using the grammar elements studied.
- Share with your partners the poster you created and decide which the most complete ones are.

Self-Assessment

Yes

No

1. I deepen my knowledge about processes in an operating system.

☐
☐

2. I express information through a poster.

☐
☐

3. I share information with partners.

☐
☐

Target Words

- **calm down** (phrasal verb): to relax after being altered
e.g. Susan, calm down. First of all, Do you know what a process in an operating system is?
- **sole** (adjective): Single, unique or individual
e.g. Its main function is run software code of an application program or tool. They ought to be created and maintained for this sole purpose.
- **consolidate** (verb): to combine or gather
e.g. In a background process, different functions ought to be consolidated, so we don't need many programs to handle.
- **act** (verb): to work or perform as something else
e.g. They act as a bridge between the background and user processes.
- **parallelism** (noun): when two or more items work at the same but do not interfere with each other
e.g. If we can use parallelism to create a better performance, reliability in the system will go up.
- **configure** (verb): to organize or arrange
e.g. All the processes ought to be configured according to the number of users and need to minimize the work and maximize the use of resources.

Learning Points

Passive of Modal Verbs: Ought To

We use the **passive voice** when we want to emphasize on the action but not on the person who does it. **Passive voice** can be used anytime with modal verbs. Let's see with **Ought to**.

Ought to is always used to talk about obligations and duties.

Example

*She **ought to** call the police. Those people are dangerous.*

When we use the **passive voice** with a **modal verb**, we simply follow the same structure of the passive and add the verb "be" after the **modal verb**. See the following structure:

Subject + ought to be + verb in past participle + complement

Examples

*The report **ought to be** finished by next Friday.*

*This road **ought to be** repaired. It is impossible for cars to go through.*

Examples

- *In a background process, different functions ought to be consolidated, so we don't need many programs to handle each user.*
- *User processes are a little different. Their main function is run software code of an application program or tool. They ought to be created and maintained for this sole purpose.*
- *All the processes ought to be configured according to the number of users and needs to minimize the work and maximize the use of resources.*

Learning Points

First Conditional Review

We use the **first conditional** to talk about possible actions in the future.

When we use **if** in the first conditional, we talk about possible events or actions happening in the future as long as the condition is given.

Structure:

If + present tense sentence + future "will" sentence

Examples:

If she **doesn't know** the address, **will** you help her?

If it **rains** tomorrow, I **will** stay at home.

We **can** also use **When** in conditionals, but it is a little different. It means that the second action is immediately after the first one is complete.

Examples

- *If I don't understand these server processes for next week, I will be in trouble!*
- *When we can use parallelism to create a better performance, reliability in the system goes up.*
